The size of the bovine genome is 3 Gb (3 billion base pairs). It contains approximately 22,000 genes of which 14,000 are common to all mammalian species. Bovines share 80 percent of their genes with humans; cows are less similar to humans than rodents (humans and rodents belong to the clade of Supraprimates).

Local imputation accuracy (R² dose) when imputing HD genotypes using the two bovine genome assemblies. Mean imputation accuracy (R² dose) for SNPs grouped in segments of 100 kb on the 29 autosomes when aligned to the ARS-UCD1.2 and UMD3.1 assemblies. For better visualisation, accuracies are plotted as means of 1-R² dose and R² dose-1 for UMD3.1 and ARS-UCD1.2 assemblies respectively.

A genome is an organism's complete set of DNA, all the information needed to build that organism. The main difference between genomics and genetics is that genetics may look at a single gene, but genomics looks at all genes and how they interact to influence growth and development of an organism. How does genomics help livestock producers?

A journey into Bovine Genomics starts thousands of years ago with archeology and the domestication of cattle to current genome association studies, genomic selection, bovine epigenetics, and the identification of quantitative trait nucleotides affecting phenotypic variation in cattle.

Genomics Genomics studies the structure, function, evolution and mapping of DNA and the genetic makeup of animals. It deals with the complete set of genes and genetic material found in a cell or organism. Genomic technologies draw both producer interest and research investment in the beef industry.

The bovine genome is made up of about 25,000-30,000 useful genes. For genomic selection, the genome researchers look for markers or single nucleotide polymorphisms (SNPs). An SNP is a place in a chromosome where the DNA sequence can differ among individuals.
