Solving Linear Equations in One Variable. A linear equation is an equation of a straight line, written in one variable. The only power of the variable is 1. Linear equations in one variable may take the form and are solved using basic algebraic operations. We begin by classifying linear equations in one variable as one of three types: identity, conditional, or inconsistent.

Linear Equations in One Variable – Algebra and Trigonometry

It is a common task in algebra to solve an equation for a variable. The goal will be to get the variable on one side of the equation all by itself and have the other side of the equation just be a number. The process will involve identifying the operations that are done on the variable and apply the inverse operation to both sides of the equation.

4.3: Solving Linear Equations in One Variable ...

Solving linear equations with one variable Linear equations in one variable are equations where the variable has an exponent of 1, which is typically not shown (it is understood). An example would be something like $12x = x - 5$. To solve linear equations, there is one main goal: isolate the variable.

As you manipulate equations to solve them, you must keep both sides balanced. Whatever you do to one side of the equation, you must do to the other side. So, if you need to add a value to isolate the variable, you must also add that same value to the other side of the equation. For example, in the equation. $x + 9 = 5$.
